

and two summation formulas

$$\sum_{i=l}^u 1 = u - l + 1 \quad \text{where } l \leq u \text{ are some lower and upper integer limits, (S1)}$$

$$\sum_{i=0}^n i = \sum_{i=1}^n i = 1 + 2 + \cdots + n = \frac{n(n+1)}{2} \approx \frac{1}{2}n^2 \in \Theta(n^2). \quad (\text{S2})$$

Note that the formula  $\sum_{i=1}^{n-1} 1 = n - 1$ , which we used in Example 1, is a special case of formula (S1) for  $l = 1$  and  $u = n - 1$ .

**EXAMPLE 2** Consider the *element uniqueness problem*: check whether all the elements in a given array of  $n$  elements are distinct. This problem can be solved by the following straightforward algorithm.

**ALGORITHM** *UniqueElements*( $A[0..n - 1]$ )

//Determines whether all the elements in a given array are distinct

//Input: An array  $A[0..n - 1]$

//Output: Returns “true” if all the elements in  $A$  are distinct

// and “false” otherwise

**for**  $i \leftarrow 0$  **to**  $n - 2$  **do**

**for**  $j \leftarrow i + 1$  **to**  $n - 1$  **do**

**if**  $A[i] = A[j]$  **return false**

**return true**

The natural measure of the input’s size here is again  $n$ , the number of elements in the array. Since the innermost loop contains a single operation (the comparison of two elements), we should consider it as the algorithm’s basic operation. Note, however, that the number of element comparisons depends not only on  $n$  but also on whether there are equal elements in the array and, if there are, which array positions they occupy. We will limit our investigation to the worst case only.

By definition, the worst case input is an array for which the number of element comparisons  $C_{\text{worst}}(n)$  is the largest among all arrays of size  $n$ . An inspection of the innermost loop reveals that there are two kinds of worst-case inputs—inputs for which the algorithm does not exit the loop prematurely: arrays with no equal elements and arrays in which the last two elements are the only pair of equal elements. For such inputs, one comparison is made for each repetition of the innermost loop, i.e., for each value of the loop variable  $j$  between its limits  $i + 1$  and  $n - 1$ ; this is repeated for each value of the outer loop, i.e., for each value of the loop variable  $i$  between its limits 0 and  $n - 2$ . Accordingly, we get

$$\begin{aligned}
C_{worst}(n) &= \sum_{i=0}^{n-2} \sum_{j=i+1}^{n-1} 1 = \sum_{i=0}^{n-2} [(n-1) - (i+1) + 1] = \sum_{i=0}^{n-2} (n-1-i) \\
&= \sum_{i=0}^{n-2} (n-1) - \sum_{i=0}^{n-2} i = (n-1) \sum_{i=0}^{n-2} 1 - \frac{(n-2)(n-1)}{2} \\
&= (n-1)^2 - \frac{(n-2)(n-1)}{2} = \frac{(n-1)n}{2} \approx \frac{1}{2}n^2 \in \Theta(n^2).
\end{aligned}$$

We also could have computed the sum  $\sum_{i=0}^{n-2} (n-1-i)$  faster as follows:

$$\sum_{i=0}^{n-2} (n-1-i) = (n-1) + (n-2) + \cdots + 1 = \frac{(n-1)n}{2},$$

where the last equality is obtained by applying summation formula (S2). Note that this result was perfectly predictable: in the worst case, the algorithm needs to compare all  $n(n-1)/2$  distinct pairs of its  $n$  elements. ■

**EXAMPLE 3** Given two  $n \times n$  matrices  $A$  and  $B$ , find the time efficiency of the definition-based algorithm for computing their product  $C = AB$ . By definition,  $C$  is an  $n \times n$  matrix whose elements are computed as the scalar (dot) products of the rows of matrix  $A$  and the columns of matrix  $B$ :

$$\begin{array}{c}
\text{row } i \\
\left[ \begin{array}{c} \boxed{\phantom{0}} \quad \boxed{\phantom{0}} \quad \boxed{\phantom{0}} \quad \boxed{\phantom{0}} \quad \boxed{\phantom{0}} \end{array} \right]
\end{array}
\begin{array}{c}
A \\
* \\
\left[ \begin{array}{c} \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \end{array} \right]
\end{array}
\begin{array}{c}
B \\
= \\
\left[ \begin{array}{c} \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \\ \boxed{\phantom{0}} \end{array} \right]
\end{array}
\begin{array}{c}
C \\
C[i,j]
\end{array}$$

col.  $j$

where  $C[i, j] = A[i, 0]B[0, j] + \cdots + A[i, k]B[k, j] + \cdots + A[i, n-1]B[n-1, j]$  for every pair of indices  $0 \leq i, j \leq n-1$ .

**ALGORITHM** *MatrixMultiplication*( $A[0..n-1, 0..n-1]$ ,  $B[0..n-1, 0..n-1]$ )  
 //Multiplies two square matrices of order  $n$  by the definition-based algorithm  
 //Input: Two  $n \times n$  matrices  $A$  and  $B$   
 //Output: Matrix  $C = AB$   
**for**  $i \leftarrow 0$  **to**  $n-1$  **do**  
   **for**  $j \leftarrow 0$  **to**  $n-1$  **do**  
 $C[i, j] \leftarrow 0.0$   
**for**  $k \leftarrow 0$  **to**  $n-1$  **do**  
 $C[i, j] \leftarrow C[i, j] + A[i, k] * B[k, j]$   
**return**  $C$
