CMPT 306 Algorithms & Data Structures Fall 2017 Homework #3 100 Total Points

Due Date: 11:59 PM Friday, October 13, 2017. Submit your answers in a file through Canvas.

Be sure to show all supporting work to receive full credit.

- 1. (30 points (6 pts each)) Solve (in closed form, not big-Theta) the following recurrences:
 - $C_n = C_{n-1} + 5$ where $C_1 = 0$.
 - $C_n = 3C_{n-1}$ where $C_1 = 4$.
 - $C_n = C_{n-1} + n$ where $C_0 = 0$.
 - $C_n = C_{(n/2)} + n$ where $C_1 = 1$. (Only need to show final result for this question.)
 - $C_n = C_{(n/3)} + 1$ where $C_1 = 1$. (Only need to show final result for this question.)
- 2. (4 points) Consider the following problem: Design an algorithm to determine the best route for a passenger to travel from one location to another using public transportation where travel may involve (a) bus, (b) light rail, (c) walking, and (d) commuter rail. For example, a passenger may have to ride a bus to one station, walk to another station where they get on light rail, then take a bus to another bus, and so forth.
 - What reasonable criteria could be used for defining the "best" route?
 - How would you model this problem as a graph?
- 3. (6 points) Describe how one can implement each of the following operations on an array so that the time it takes does not depend on the array size n.
 - ullet Delete the i^{th} element of an unordered array of size n.
 - Delete the *i*th element of an ordered array, where the array remains in sorted order after the deletion.
- 4. (12 points) List the following expressions from best(lowest) to worst(highest) order. If any expressions are of the same order, indicate that they are equal. (Note lg refers to log_2)

$$2^{n}$$
, $n-n^{2}+5n^{3}$, 2^{n-1} , $lq n$, n^{3} , $n lq n$, n^{2} , \sqrt{n} , 42 , n , $(3/2)^{n}$, $n!$, $n^{3}+lq n$

- 5. (8 points) Algorithms W, X, Y, and Z are analyzed and found to have worst-case running times no greater than $20 \times Nlog_{10}N$, $5 \times N^2$, $.005N^3$, and $5000 \times N$ respectively. Answer the following questions:
 - (4 points) What is the big-theta notation of each of these four algorithms?
 - (4 points) Using your answer from the question above, what is the ordering of these four algorithms from best(lowest) to worst(highest)?
- 6. (20 points) Consider the following Python code:

```
def mystery(n):
    s = 0

for i in range(1,n+1):
    s = s + i * i

return s
```

- (6 points) What does mystery() compute?
- (2 point) What is its basic operation?
- (2 point) How many times is its basic operation executed?
- (4 points) What is its efficiency using Big-Theta notation?
- (6 points) Can you suggest an improvement to this algorithm? If so, what is the efficiency class of your improvement? Otherwise, try to provde that it cannot be done.
- 7. (20 points) Consider the following recursive algorithm for computing the sum of the first n cubes: $S(n) = 1^3 + 2^3 + ... + n^3$:

```
def sum(n):
    if n == 1:
        return 1
    else:
        return sum(n-1) + n * n * n
```

- (12 points) Set up and solve a recurrence relation for the number of times the algorithm's basic operation is performed.
- (8 points) How does this algorithm compare with the straightforward, nonrecursive algorithm for computing this sum?
